BEST AVAILABLE IMAGES

Defective images within this document are accurate representations of the original documents submitted by the applicant.

Defects in the images may include (but are not limited to):

- BLACK BORDERS
- TEXT CUT OFF AT TOP, BOTTOM OR SIDES
- FADED TEXT
- ILLEGIBLE TEXT
- SKEWED/SLANTED IMAGES
- COLORED PHOTOS
- BLACK OR VERY BLACK AND WHITE DARK PHOTOS
- GRAY SCALE DOCUMENTS

IMAGES ARE BEST AVAILABLE COPY.

**As rescanning documents *will not* correct images,
please do not report the images to the
Image Problem Mailbox.**

REMARKS

This is in response to the Office Action of January 30, 2001 and the advisory action of March 22, 2002. In view of the foregoing amendments and following representations, reconsideration is respectfully requested. Note that the arguments set forth in the Request for Reconsideration are represented below to ensure full consideration by the Examiner.

* * * * *

In the previous Office Action, claims 8-11, 13-15 and 18-28 are rejected over the prior art, with the Examiner particularly relying on Dornes (U.S. Patent No. 4,573,262) and JP 63178596. The Examiner is respectfully requested to reconsider the rejections in view of the foregoing amendments and following remarks.

In the present invention, the first mounting head section is capable of mounting a plurality of picked-up components onto a board, while the second mounting head section successively picks up (by suction) a plurality of components at the other of the component supply tables. Therefore, during an operation of the one mounting head section, such as a component sucking operation or a component mounting operation, it is possible to prevent the other mounting head section from moving over a large range of the board and the component supply tables, thereby preventing the occurrence of large vibrations caused by such movements. Accordingly, component sucking and mounting operations can be performed with a high degree of accuracy.

Furthermore, each of the independent claims now requires that at least one of the mounting heads has a plurality of nozzles that are rotatably supported for successively picking up components.

In contrast, each of the **Dornes** and **JP 63178596** references merely teaches respective operations of two heads. However, neither reference teaches or suggests any apparatus that would operate so as to prevent the occurrence of large vibrations caused by such movements over a large range of the board and the component supply tables. That is, when two heads are respectively and independently operated during sucking and mounting operations, one head carries out a sucking or mounting operation, while the other head carries out such movements over a large range of the board and the component supply tables. The movements involved in these operations generate large vibrations, which deteriorate the quality of the sucking or mounting operations. In addition, the components stored in the component supply tables might shift due to the above-described vibrations, thereby resulting in sucking operation failures.

For example, when the one head starts to move from the component supply table to the board, and when the one head stops at the board, large vibrations can be generated due to the start and stop (**i.e., the acceleration and deceleration**) of the one head, and in turn, the generated vibrations can affect the sucking and mounting operations of the other head. That is, the other head may be subjected to the large vibrations generated by the operation of the one head, and thus, the positions of the components held by the other head may shift, thereby reducing the accuracy of the component mounting operation.

In general, in the prior art apparatuses, in order to prevent the operations from being affected by such large vibrations, after starting or stopping the one head, the operation of the other head should be stopped for a certain amount of time. The necessity to stop the operation of the other head undesirably increases the processing time.

Furthermore, when processing time is reduced, and the moving speeds of the heads are increased, the above-described vibrations may also increase, thus making it necessary to increase the stop time.

According to JP 63178596, as described on page 11, lines 22-28 of the translation, when a collision or the like is judged to be possible in step 4, the head is stopped, thus avoiding the collision or the like. That is, in JP 63178596, when the one head carries out a component mounting operation, the other head moves to a board for a component mounting operation and then stops near the one head. This means that large vibrations may be generated by the start and stop of the other head, which may result in adverse effects, such as reduced accuracy of the mounting operation of the one head. Accordingly, in order to avoid such adverse effects, the mounting operation of the one head should be stopped from the start to the stop of movement of the other head in addition to a certain amount of time after the stop of movement, which results in increased processing time.

In contrast, in the present invention, the negative effects caused by the acceleration or deceleration of any of the heads is avoided because, when one head carries out a sucking operation, the other head carries out a mounting operation. This arrangement

does not result in increased processing time because **there is no waiting time to avoid the negative affects of generated vibrations.** Thus, the present invention can reduce the processing time in comparison with the applied prior art references. Note, each of independent claims 8, 18 and 24 requires that the first mounting head section be capable of mounting the plural picked-up components onto the board while the second mounting head section successively picks up the plural components at the other of the component supply tables. Clearly, any combination of Dornes and JP 63178596 would not disclose first and second mounting heads that are capable of operating in the manner specified in the independent claims.

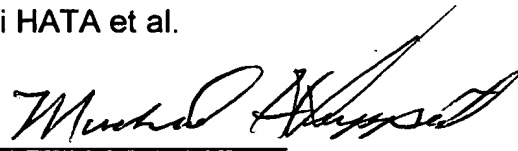

Therefore, it is submitted that the collective teachings of the Dornes and JP 63178596 does not teach or suggest the novel features of the present invention, as set forth in independent claims 8, 18 and 24. The Examiner therefore is requested to pass this application to issue.

In the event that the Examiner has any comments or suggestions of a nature necessary to place this case in condition for allowance, then the Examiner is requested to contact Applicant's undersigned attorney by telephone to promptly resolve any remaining matters.

Respectfully submitted,

Kanji HATA et al.

8.(Five Times Amended) A component mounting apparatus comprising:

a pair of component supply tables for accommodating a plurality of components, said component supply tables being arranged on opposite sides of a board mounting position;

a first mounting head section having a plurality of rotatably supported component suction nozzles, wherein the first head section can rotate the component suction nozzles for successively [sucking to pick] picking up the plural components at one of the component supply tables by suction, thereafter the first mounting head section is moved [moving] to a board positioned at the board mounting position, and thereafter the plural picked-up components are successively mounted [mounting the plural picked-up components] onto the board while the first mounting head section is moved [moving] in first and second directions which are perpendicular to each other,

wherein the first direction is perpendicular to a direction in which the board is transferred, and the second direction is located along the board transfer direction; and

a second mounting head section having a plurality of rotatable component suction nozzles, wherein the second head section is capable of rotating the component suction nozzles for successively [sucking to pick] picking up the plural components at the other of the component supply tables by suction, thereafter the second mounting head section moves the component suction nozzles [moving] to the board positioned at the board mounting position, and thereafter the plural picked-up components are successively mounted [mounting the plural picked-up components] onto the board while the second

mounting head moves [moving] in third and fourth directions which are perpendicular to each other,

wherein the third direction is parallel to the first direction, and the fourth direction is parallel to the second direction but is not necessarily the same as the second direction,

wherein each of the first and second mounting head sections is independently moveable between the component supply table and the board, and the first mounting head section is capable of mounting the plural picked-up components onto the board while the second mounting head section successively sucks to pick up the plural components at the other of the component supply tables.

18. (Twice Amended) A component mounting apparatus comprising:

a pair of component supply tables for accommodating a plurality of components, said component supply tables being arranged on opposite sides of a board mounting position;

a first mounting head section for successively picking up the plural components at one of the component supply tables and thereafter successively mounting the plural picked-up components onto a board, positioned at the board mounting position, while moving in first and second directions which are perpendicular to each other,

wherein the first direction is perpendicular to a direction in which the board is transferred, and the second direction is located along the board transferred, and the second direction is located along the board transfer direction; and

a second mounting head section for successively picking up the plural components at the other of the component supply tables and thereafter successively mounting the plural picked-up components onto the board, positioned at the board mounting position, while moving in third and fourth directions which are perpendicular to each other,

wherein the third direction is parallel to the first direction, and the fourth direction is parallel to the second direction but is not necessarily the same as the second direction,

wherein each of the first and second mounting head sections is independently movable between the component supply table and the board,

wherein one of the first and second mounting head sections has a plurality of rotatably supported component suction nozzles for sucking a plurality of the components prior to a component mounting operation, and the one mounting head section is capable of rotating the component suction nozzles.

wherein the first mounting head section mounts the plural picked-up components onto the board while the second mounting head section successively sucks to pick up a plurality of the [plural] components at the other of the component supply tables.

24. (Twice Amended) A component mounting apparatus comprising:

a pair of component supply tables for accommodating a plurality of components, said component supply tables being arranged on opposite sides of a board mounting position;

a first mounting head section having a plurality of nozzles that are rotatably supported for successively picking up more than one of the components at one of the component supply tables and thereafter successively mounting the picked-up components on a board that is positioned at the board mounting position, said first mounting head section being movable in first and second directions which are perpendicular to each other,

wherein the first direction is perpendicular to a direction in which the board is transferred, and the second direction is along the direction in which the board is transferred; and

a second mounting head section having a plurality of component suction nozzles that are rotatably mounted for successively picking up more than one of the components at the other of the component supply tables and thereafter successively mounting the picked-up components on the board, positioned at the board mounting position, while the second mounting head section moves [moving] in third and fourth directions which are perpendicular to each other,

wherein the third direction is perpendicular to a direction in which the board is transferred, and the fourth direction is along the direction in which the board is transferred;

wherein each of the first and second mounting head sections is independently movable between the component supply tables and the board,

wherein the first mounting head section is capable of mounting the plural picked-up components on the board while the second mounting head section successively picks up the plural components at the other of the component supply tables.
